ABSTRACT

Background: Profunda femoris artery (PFA) is the largest and deep branch from the femoral artery. It is the chief blood supply to the extensor (anterior), flexor (posterior) and adductor (medial) compartments of thigh. It is also called as Deep femoral artery. It is useful for many invasive and non invasive procedures like Doppler, ultrasonography, digital subtraction angiography arteriography and magnetic resonance imaging etc.

Materials and methods: A total 10 embalmed formalin fixed cadavers (totally 20 lower limbs) allotted to the undergraduates of 2017-18 batch in the department of Anatomy, Tirunelveli Medical College, Tirunelveli is taken in the present study.

Results: In all the 20 lower limb specimens PFA was originated from the femoral artery except one. In one specimen PFA originated directly from external iliac artery as the bifurcation of external iliac artery. Relation of PFA with femoral artery was postero lateral in 65% and lateral in 35%.

Distance between the point of origin of PFA and mid-inguinal point was between 3.47cm to 4.55cm in 90 %.

Conclusion: This study will be very helpful to the radiologists & surgeons to understand possible variations before planning different diagnostic and therapeutic interventions on the femoral artery and its branches.

KEY WORDS: Profunda femoral artery, Femoral artery and Mid-inguinal point.

INTRODUCTION

Profunda femoris artery (PFA) is the largest and deep branch from the femoral artery. It is the chief blood supply to the extensor (anterior), flexor (posterior) and adductor (medial) compartments of thigh. It is also called as Deep femoral artery.

Profunda femoris artery usually arises from the postero-lateral side of femoral artery. The origin of profunda femoris artery is about nearly 3.5cm from the mid-inguinal point (Mid-point between the anterior superior ilac spine and pubic symphysis). It leaves the femoral triangle by passing between pectines & adductor longus, then between the adductor longus and adductor brevis and then between the adductor longus and adductor magnus. Finally continuous as fourth perforating artery after piercing the adductor magnus. In the femoral triangle it gives medial circumflex femoral artery, lateral.
circumflex femoral artery, muscular branches and perforating arteries. It is useful for many invasive and non invasive procedures like Doppler, ultrasonography, digital subtraction angiography arteriography and magnetic resonance imaging etc. Its branches also form feeder arteries for many cutaneous and musculo-cutaneous flaps.

**Objectives**

The main objectives of this study is
1) To know the pattern of origin of profunda femoris artery.
2) To know the relation between the profunda femoris artery and femoral artery.
3) To know the distance between mid-inguinal point and the point of origin of PFA

**MATERIALS AND METHODS**

A total 10 embalmed formalin fixed cadavers (totally 20 lower limbs) allotted to the undergraduates of 2017-18 batch in the department of Anatomy, Tirunelveli Medical College, Tirumelveli is taken in the present study. This study was conducted by the dissection method described in the Cunningham’s Manual of Practical Anatomy. First skin was incised and reflected along with superficial fascia. Then deep fascia is reflected and femoral sheath was removed. Femoral artery along with femoral vein was dissected. Femoral vein was medial to femoral artery. Femoral artery traced proximally up to mid-inguinal point and branches of femoral artery including Profunda femoris artery also traced. The origin of profunda femoris artery and relation with femoral artery was studied. The distance between the mid-inguinal point to point of origin of profunda femoris artery was measured using digital vernier caliper.

**RESULTS**

**Point of origin of PFA:** In all the 20 lower limb specimens PFA was originated from the femoral artery except one. In one specimen PFA originated directly from external iliac artery as the bifurcation of external iliac artery. (Fig 1)

**Position of the PFA in relation to Femoral artery:** Table 1 shows the percentage of different positions of profunda femoris artery in relation with femoral artery. Out of 20 specimens, in 13 specimens profunda femoris artery was poster-lateral to femoral artery and in remaining 7 specimens it was lateral to femoral artery. (Fig 2), (Fig 3)

**Distance between the point of origin of PFA and mid-inguinal point:** The table 2 shows the readings of all 20 specimens. Among the 20 lower limb specimens, in 18 specimens (90%) the distance between the point of origin of PFA and mid-inguinal point between 3.47cm to 4.55cm. Only two specimens (10%) having higher origin of PFA. In one specimen (5%) the distance between the point of origin of PFA and mid-inguinal point is 1.65cm. In only one specimen (5%) PFA is directly arises from external iliac artery. (Fig 4 & 5)

**Table 1:** Relation of PFA with femoral artery.

**Fig. 2:** Postero-lateral Relation of PFA with femoral artery

**Fig. 3:** Lateral relation of PFA with femoral artery.

**Fig. 4 & 5:** The distance between the origin of PFA and mid-inguinal point—By Using vernier calliper.

**DISCUSSION**

**Point of origin of PFA:** In all the studies, the profunda femoris artery arises from the femoral artery. But in this study out of 20 specimen, in one specimen profunda femoris arose from external iliac artery (Bifurcation of External iliac artery)

**Table 3:** Position of the PFA in relation to Femoral artery:

</tbody>
</table>

Most of the above studies, PFA is postero lateral to femoral artery. This study also correlated with the above study and PFA is postero lateral to FA.

**Distance between the point of origin of PFA and mid-inguinal point:** According to Susen Grey and Richard Snell [9,10], the distance between the origin of PFA and MIP is 3.5 cm to
4 cm. In many cases, deviation was noted where PFA originated above or below this point. In the present study, 90% specimens the distance between the origin of PFA and MIP was between 3.47 cm to 4.55 cm and 10% specimens having higher origin of PFA ie 0 -1.65 cm. Dixit et al 2001, studied that the low origin was found in only one limb and the range was 7.7-8.8 cm. In Brijesh R et al (2015) [2] only 2 right limbs showed where PFA originated at a lower level and distance was 7.1-8.0 cm. MB Samarawickrama et al [5] study the level of origin of the profunda femoris was varying from 3.0 to 7.0 cm from the mid point of the inguinal ligament.

CONCLUSION

Sound anatomical and embryological knowledge of branching pattern of femoral artery is important while performing clinical procedures in femoral region such as catheterization, surgical intervention of embolism, angiography, colour Doppler flow imaging, repair of femoral hernia, musculocutaneous flaps, and vascular reconstructive surgeries. This study will be very helpful to the radiologists & surgeons to understand possible variations before planning different diagnostic and therapeutic interventions on the femoral artery and its branches.

ABBREVIATIONS

PFA – Profunda femoris artery
FA – Femoral artery
MIP – Mid- Inguinal Point
